

Lesson 2 – Estimating the Instantaneous Rate of Change

Terminology

Instantaneous Rate of Change: An estimate of the rate of change of a function $y = f(x)$ at a specific value of the independent variable $x = a$; estimated using average rates of change for small intervals of the independent variable very close to $x = a$. THE SLOPE OF THE TANGENT LINE

Preceding Interval: an interval of the independent variable of the form $a - h \leq x \leq a$, where h is a small positive value; used to determine an average rate of change.

Following Interval: an interval of the independent variable of the form $a \leq x \leq a + h$, where h is a small positive value; used to determine an average rate of change.

Centered Interval: an interval of the independent variable of the form $a - h \leq x \leq a + h$, where h is a small positive value; used to determine an average rate of change. The instantaneous rate of change can be estimated by squeezing the centered intervals

Difference Quotient: if $P(a, f(a))$ and $Q(a + h, f(a + h))$ are two points on the graph of $y = f(x)$, then the instantaneous rate of change of y with respect to x at P can be estimated using

THE DIFFERENCE QUOTIENT

$$\frac{\Delta y}{\Delta x} = \frac{f(a + h) - f(a)}{h}$$

where h is a very small number. This expression is called the difference quotient.

Example 1

A small pebble is dropped into a 3.0m tall cylindrical tube filled with thick glycerine. A motion detector recorded the time and the total distance that the pebble fell after its release.

Time, t (s)	6.0	6.2	6.4	6.6	6.8	7.0
Distance, $d(t)$ (cm)	208.39	221.76	235.41	249.31	263.46	277.84

- a) Estimate the instantaneous rate of change when $t = 6.4$ seconds using the preceding interval method.
