Abstract:

Expansive soils exhibit volume instability, cyclic swell-shrink behavior and low strength. These soils are improved by various stabilization methods. Stabilization of such soils includes both physical stabilization and chemical stabilization. Attempts have been made by many researchers in trying to proffer solutions to this defect by experimenting in innovative ways with different materials that could possibly improve the soil engineering properties and reduce environmental hazards. A more effective and efficient use of natural resources make it suitable for construction and as well be very cost effective. Currently there are large volumes of materials considered as wastes or by-products produced by industrial activities. Wastes from different industries have been used for this purpose. This paper highlights the results of works done by different researchers on stabilization of expansive soil using stone waste materials as soils stabilizers and for decreasing the environmental hazards. The results of laboratory tests such as unconfined compression strength test (UCS), California bearing ratio (CBR), free swell index, liquid limit, plastic limit, compaction, etc. were presented and discussed in this paper.

Keywords: Expansive soils, stabilization, stone waste, environmental hazards.

Expansive Soils:

Expansive soil problems can occur in both arid and semi-arid soils and humid environments. The engineering properties and behavior of these problematic soils change drastically, they would get increased in volume and hence they would swell. On the other hand, the shrinkage happens when the soil gets dry [1-3]. The excessive movements resulted from these problematic soils can lead to both damage and negative impact on roads, buildings, pipelines, and other structural members which is even more than twice the damage resulted from hurricanes floods, earthquakes, and tornadoes. Understanding the behavior and characteristics of these types of soils can help scientists to control the imposed damages to the structures, [4]. Expansive soil problems usually happen because of the changes in the water content in the upper few meters, with deep seated heave being rare. The climate and environmental parameters considerably affect the water content in these upper layers. The water content is generally termed the zone of seasonal fluctuations or active zone [1]. Expansive soil is a highly plastic soil that normally contains montmorillonite and other active clay minerals. Some clay minerals such as, montmorillonite have the greatest volume change in comparison to all the
