

Evolution & Natural Selection

DOODLE NOTES

GENETIC Evolution

natural selection changes the range of traits in a population - there are 3 ways it can change. Let's look at a multi population that shows

Evolution by natural selection

Describe the theory of natural selection and how the theory was first conceived (thought of).

An English naturalist named Charles Darwin went on a voyage around the world. He noticed that animals in similar environments had similar characteristics. For example, in the Galápagos islands, Darwin observed similar but non-identical species of finches on each island. He noticed that their beaks seemed to be adapted to their food source. After some time thinking and the work of other scientists, Darwin developed his theory of natural selection.

Individuals with favorable traits survive and reproduce, passing on those traits to their offspring. Over time, the population becomes better adapted to its environment.

An example of natural selection!

<p>A population of light brown mice lives in an area of dark rock. They have two traits:</p>	<p>One day a hawk comes to hunt for the common variation.</p>
<p>Some mice have dark fur. They are camouflaged against the dark rock where they live.</p>	<p>The light brown mice are more likely to get eaten - they are the birds' favorite!</p>
<p>A higher proportion of black mice are born in the next generation.</p>	<p>Over time, the population has changed so that most of the mice have black fur.</p>

Stabilizing selection

Stabilizing selection is a type of natural selection that favors the average phenotype and selects against extreme variations. It results in a population with a narrow range of traits.

GENE FLOW

What is it? Movement of genes in or out of a population. It happens through movement of individuals or gametes. It can bring new alleles into a population or change the frequency of existing alleles.

Example: A population of butterflies with a mix of colors. A new color is introduced from another population.
