attempts to conserve the multiple voltage states i.e. consumes the available states densely or compactly Using the multiple voltage states originally for securing more storage capacity for the service of multiple write operations per a single erase operation can enhance device lifetime in scenarios where there is no need of such a large storage capacity As for case iii motivated by our observation that the state of the art over provisioned OP flash capacity partitioning strategies are not optimal from a device lifetime angle while they certainly help to provide a guaranteed service level to each of co running workload we propose a strategy using which one can explore the OP partitioning space and determine a lifetime optimal OP partitioning that minimizes the collective number of write operations coming from garbage collection GC thus maximizing device lifetime Our extensive experimental evaluations based on simulation I/O traces from real workloads for cases i and ii and emulation real applications for case iii demonstrate that our proposed techniques i ii and iii can improve the device lifetime by 6.8x 27.9% and 43% on average respectively against a conventional SLC flash a conventional MLC flash and a state of the art lifetime agnostic OP partitioning strategy Also all our proposed approaches lead to improved performance e.g. response time and throughput or provide at least the same level of performance when compared to a baseline that does not consider device lifetime explicitly

Characterization of TLC Flash Memory Zachary Taylor Blair, 2017 Flash memory manufacturers are increasing storage density by leveraging multi bit per cell NAND flash technology in the latest process nodes Error rates and endurance can be significantly altered in each generation and the manufacturers provide conservative guidelines for these metrics Deeper understanding of the physical characteristics of flash devices can be used to develop a usage model which improves lifetime and reliability We developed a System on Chip SoC platform for flash memory testing including a hardware memory controller and software for pattern generation and data processing We have used the platform to characterize properties of a Triple Level Cell TLC flash memory device from a single vendor and found behaviors have significantly changed from previous generations Among these novel findings manufacturers have built compensation mechanisms for some worst case behaviors such as inter cell interference ICI but other effects become inherently more significant in the latest technologies With information about how certain behaviors affect reliability in both the short term and toward the end of the product lifetime this work provides speculation on the goals for coding schemes which target error mitigation

Inside NAND Flash Memories Rino Micheloni, Luca Crippa, Alessia Marelli, 2010-07-27 Digital photography MP3 digital video etc make extensive use of NAND based Flash cards as storage media To realize how much NAND Flash memories pervade every aspect of our life just imagine how our recent habits would change if the NAND memories suddenly disappeared To take a picture it would be necessary to find a film as well as a traditional camera disks or even magnetic tapes would be used to record a video or to listen a song and a cellular phone would return to be a simple mean of communication rather than a multimedia console The development of NAND Flash memories will not be set down on the mere evolution of personal entertainment systems since a new killer application can trigger a further success the

replacement of Hard Disk Drives HDDs with Solid State Drives SSDs SSD is made up by a microcontroller and several NANDs As NAND is the technology driver for IC circuits Flash designers and technologists have to deal with a lot of challenges Therefore SSD system developers must understand Flash technology in order to exploit its benefits and countermeasure its weaknesses Inside NAND Flash Memories is a comprehensive guide of the NAND world from circuits design analog and digital to Flash reliability including radiation effects from testing issues to high performance DDR interface from error correction codes to NAND applications like Flash cards and SSDs

Resistive Random Access Memory Liang Zhao,2015 Recently the rapid development of big data and internet of things has fueled a surge of demand for semiconductor memories As the scaling of NAND flash is hitting its physical limits several emerging non volatile memory technologies are being studied intensively to enable higher memory density and better performance Among them resistive random access memory RRAM has attracted tremendous interests due to its ability to overcome the inherent limitations of flash memory while also delivering cost effectiveness robust performance and small footprint Despite its promising features several challenges remain to be addressed for the future development and commercialization of RRAM technology First of all the physical mechanisms behind resistance change phenomena have not been fully understood making it difficult to optimize the device performance Secondly the reliability of RRAM should be improved in several aspects such as the variability of switching parameters the retention endurance failures caused by the random nature of filament formation as well as the

requirement for a high voltage forming process Moreover it is also highly desired to stack RRAM devices in a 3D architecture and or develop multi level storage capability to reduce the cost per bit and compete with NAND flash This thesis presents an in depth analysis of some state of the art techniques to tackle these challenges from three aspects the materials the device structure as well as the characterization methods From the material s perspective doping technology of RRAM is investigated as an approach to improve RRAM performance Ab initio modeling and simulations are applied to study the effects of dopant types dopant concentrations oxide phases and oxide stoichiometry on the electronic and thermodynamic properties of oxygen vacancies in HfO₂ The physical insights derived from the calculations provide guidelines to achieve desirable RRAM characteristics through doping In the aspect of electrical characterization the pulse train characterization techniques are developed for the multi level control and in depth physical understanding of conductive filament evolution By adopting pulse train operation for an RRAM device with 3 bit potential the relative standard deviations of resistance levels are improved up to 80% compared to the single pulse scheme The observed exponential relation between the saturated resistance and the pulse amplitude provides supporting evidence for the gap formation model during the RESET process of RRAM From the device structure point of view the feasibility of ultra thin HfO₂ RRAM is investigated which helps to achieve the forming free property and low power operation The theoretical scaling limit of HfO_x thickness is first estimated using density functional theory within the non equilibrium Green s function formalism The feasibility of 2 nm HfO_x RRAM is predicted for large area devices and verified by fabricating both planar and 3D vertical RRAM devices The 3D ultra thin devices demonstrate promising characteristics including ON OFF ratio 100 switching speed 20 ns endurance 10⁸ cycles and data retention 10 years at room temperature In contributing to these areas this thesis aims at advancing both the fundamental understanding and practical implementation of RRAM technology towards the vision of high density mass storage applications

Endurance Characterization and Improvement of Floating Gate Semiconductor Memory Devices Faraz I. Khan, 2009 Low power consumption virtually zero latency extremely fast boot up for OS and applications fast data access portability and high shock resistance are some of many reasons that make Flash memory devices an ideal choice for a vast variety of consumer electronics Flash memory is a specific type of non volatile EEPROM A typical Flash memory cell looks similar to a MOSFET except that it has a dual gate structure Flash memory cells use the principle of threshold voltage modulation to alter the channel current I_{ds} when a reference read voltage V_{read} is applied to the control gate Different levels of I_{ds} are in turn interpreted as unique logic states Fowler Nordheim tunneling is used to achieve threshold voltage modulation in NAND Flash memory cells Despite its high performance potential NAND Flash memory suffers from the drawback of limited program erase endurance High field current stress caused by Fowler Nordheim tunneling during program erase cycling leads to tunnel oxide degradation which eventually limits the endurance characteristics of NAND Flash memory cells One of the most significant tunnel oxide degradation mechanisms is charge trapping This work is devoted to the study of charge trapping and

its effects on the endurance characteristics and reliability of NAND Flash memory devices Cell threshold voltage shift and memory window narrowing a direct consequence of tunnel oxide degradation caused by charge trapping are typical failure modes in NAND Flash memory cells In this work endurance characterization of NAND Flash memory devices and a detailed analysis has been conducted reconfirming the issue of limited program erase endurance Subsequently a novel NAND Flash memory cell design has been proposed which eliminates tunnel oxide degradation caused by Fowler Nordheim tunneling Device simulations using the Sentaurus TCAD tool suite by Synopsys Inc and corresponding analysis show that as compared to conventional cells the proposed cell design offers a 10 times reduction in intrinsic threshold voltage shift That according to the measured endurance characteristics of cells fabricated in this work translates to an improvement of over 200 times in program erase endurance In a nutshell the proposed cell design offers superior reliability and endurance as compared to conventional NAND Flash memory cells
