The study of what can be computed by a team of autonomous mobile robots originally started in robotics and AI has become increasingly popular in theoretical computer science especially in distributed computing where it is now an integral part of the investigations on computability by mobile entities. The robots are identical computational entities located and able to move in a spatial universe they operate without explicit communication and are usually unable to remember the past they are extremely simple with limited resources and individually quite weak. However collectively the robots are capable of performing complex tasks and form a system with desirable fault tolerant and self stabilizing properties. The research has been concerned with the computational aspects of such systems. In particular the focus has been on the minimal capabilities that the robots should have in order to solve a problem. This book focuses on the recent algorithmic results in the field of distributed computing by oblivious mobile robots unable to remember the past. After introducing the computational model with its nuances we focus on basic coordination problems: pattern formation, gathering, scattering, leader election as well as on dynamic tasks such as flocking. For each of these problems we provide a snapshot of the state of the art reviewing the existing algorithmic results. In doing so we outline solution techniques and we analyze the impact of the different assumptions on the robots' computability power.

As we approach the new millennium robots are playing an increasingly important role in our everyday lives. Robotics has evolved in industrial and military applications and unmanned space exploration promises the continued development of ever more complex robots. Over the past few decades research has focused on the development of autonomous mobile robots: robots that can move about without human supervision. This brings with it several problems, however specifically the problem of localization: How can the robot determine its own position and orientation relative to the environment around it? Various methods of localization in mobile robots have been explored. Most of these methods however assume some a priori knowledge of the environment or that the robot will have access to navigation beacons or Global Positioning Satellites. In this thesis the foundations for feature based localization are explored. An algorithm involving the Rough transform of range data and a neural network is developed which enables the robot to find an unspecified number of wall like features in its vicinity and determine the range and orientation of these walls relative to itself. Computation times are shown to be quite reasonable and the algorithm is applied in both simulated and real world indoor environments.
