

Chapter 24: The Origin of Species

Overview

1. What was Darwin's "theory of speciation"?

Speciation

2. Define speciation.

An evolutionary process in which one species splits into two or more species.

3. Distinguish between microevolution and macroevolution.

Microevolution is evolutionary change below the species level; change in the allele frequencies in a population over generations.

Macroevolution is evolutionary change above the species level—for example, the origin of new groups of organisms, such as mammals or flowering plants, through a series of speciation events.

Concept 24.1 The biological species concept: reproductive isolation

- a. Use the biological species concept to define species.

A species is a population or group of populations whose members have the potential to interbreed in nature and produce viable, fertile offspring, but do not produce viable, fertile offspring with members of other such groups.

- b. What is required for the formation of new species?

It requires an reproductive isolation. There are a number of barriers that can prevent gene flow, usually divided into prezygotic barriers and postzygotic barriers.

- c. What are hybrids?

Hybrids are offspring that result from the mating of individuals from two different species or from two true-breeding varieties of the same species.

- d. Explain the two types of barriers that maintain reproductive isolation.

Prezygotic barriers are reproductive barriers that impede mating between species or hinder fertilization if interspecific mating is attempted.

Postzygotic barriers are reproductive barriers that prevent hybrid offspring produced by two different species from developing into viable, fertile adults.
