

Failure Prediction And Detection In Cloud Datacenters

Purvil Bambharola, Prajeet Bhavsar, Vivek Prasad

Abstract: Cloud computing is a novel technology in the field of distributed computing. Usage of Cloud computing is increasing rapidly day by day. In order to serve the customers and businesses satisfactorily, fault occurring in datacenters and servers must be detected and predicted efficiently in order to launch mechanisms to tolerate the failures occurred. Failure in one of the hosted datacenters may propagate to other datacenters and make the situation worse. In order to prevent such situations, one can predict a failure proliferating throughout the cloud computing system and launch mechanisms to deal with it proactively. One of the ways to predict failures is to train a machine to predict failure on the basis of messages or logs passed between various components of the cloud. In the training session, the machine can identify certain message patterns relating to failure of data centers. Later on, the machine can be used to check whether a certain group of message logs follow such patterns or not. Moreover, each cloud server can be defined by a state which indicates whether the cloud is running properly or is facing some failure. Parameters such as CPU usage, memory usage etc. can be maintained for each of the servers. Using these parameters, we can add a layer of detection where in we develop a decision tree based on these parameters which can classify whether the passed in parameters to the decision tree indicate failure state or proper state.

1 INTRODUCTION

Cloud computing is one of the new buzzwords in the world of computer science and engineering. One of the main features that cloud service providers offers its customers is the ability to pay per use. Cloud computing also incorporates self-service and thus aiming at Autonomic computing. It also aims at providing businesses with a scalable and adaptive environment. Businesses are provided with various deployment models to choose from. Some of the deployment models include public cloud, Public cloud hosts all the data and resources on public servers which can be accessed by everyone. Private cloud is another type of model where the data is hosted on datacenters located on premise locations. Community cloud is another type of model where a set of organizations or businesses share a cloud datacenter. Hybrid model is a solution to insufficient capacity of the private cloud. Organizations are provided with an ability to subscribe to public cloud services when facing insufficient resources. This is termed as "cloud bursting" [1]. According to [1], cloud provides myriad of advantages which the local data centers cannot. These includes scalability, data security, fault tolerance, pay per use, dynamic resource allocation and much more. As a result, many giant organizations and local businesses are opting to migrate the local data in datacenters onto the cloud. It provides a level of abstraction and thus obviates the need for the users to manage the complex hardware and infrastructure. Being said that, there are many Quality of Service (QoS) parameters which the cloud service providers (CSPs) need to provide as per the Service Level Agreements (SLAs) with their customers. One important parameter is availability of resources [2].

The proliferation of distributed internet services has reaffirmed the need for reliable and high performance networks not only in the WAN bringing users to the services but within the datacenters where services themselves reside Services consist of distributed applications running across thousands of servers within datacenters with stringent performance scaling and reliability requirements To support these requirements datacenter networks are comprised of thousands of servers links and ports and over hundreds of switches providing multiple paths between any pair of servers Because any given component has a small but non zero failure rate the large number of components means that failures are endemic inside datacenters Unfortunately not all failures are easily diagnosable within datacenter environments In particular datacenters are susceptible to insidious parasitic performance loss due to a class of network component fault known as partial faults where a component is nominally healthy but intermittently drops or delays traffic These faults have been noted as being particularly difficult to detect and localize though mitigation can be straightforward once the faulty component is determined Pinpointing partial faults quickly is crucial because they are capable of inflicting a disproportionately high toll on application performance Unfortunately partial faults can confound existing fault detection methods in several ways including interactions between the fault itself application traffic characteristics and networking hardware For example network switches may fail to detect a fault due to unreliable or otherwise insensitive monitoring capabilities Traffic volume and variability may complicate analysis of server based application and network metrics as well as mask fault impact Moreover the myriad paths available to network flows complicate localization even if servers do detect partial faults However this work shows that the scale and regular design of contemporary datacenters can simplify partial fault localization In particular the combination of large scale load balanced multipath topologies and high volume datacenter traffic enables simple low overhead application agnostic and root cause agnostic partial fault localization via passive link by link outlier analysis of application network performance I validate the effectiveness of my approach within large scale first party production datacenters and examine the additional challenges and complexities raised by third party cloud datacenters

Online Failures Detection for Parallel Computing Systems Based on Time Prediction Information Ting-Yu Lin, 2019 *Hardening Cloud and Datacenter Systems Against Misconfigurations* Tianyin Xu, 2017 Misconfigurations a k a configuration errors from a system s standpoint are among the dominant causes of today s catastrophic system failures that turn down cloud scale services and affect hundreds of millions of end users Despite their wide adoption traditional fault tolerance and failure recovery techniques are not effective in dealing with configuration errors especially in large scale software systems deployed in cloud and datacenters To make the matters worse even the tolerance and recovery mechanisms themselves are often misconfigured in the real world which impairs the immune system of the entire cloud and datacenters This dissertation explores two fundamental questions towards the solutions for the inevitable misconfigurations how to build reliable cloud and datacenter systems in the face of configuration errors moreover how to prevent misconfigurations in the first place by better configuration design The goal is to enable software systems to proactively anticipate and defend against misconfigurations rather than reacting to their manifestations and consequences This dissertation presents three key principles of systems design and implementation for hardening cloud and datacenter systems against misconfigurations

anticipating misconfigurations early detection of configuration errors and simplicity oriented configuration design The dissertation demonstrates that applying these principles can effectively defend cloud and datacenter systems against misconfigurations Moreover the dissertation presents the corresponding techniques and tool support that can automatically and systematically apply these principles to existing systems software The main technical insight is that configurations are essentially used by the systems while configuration errors are mostly manifested through the faulty execution that uses erroneous configuration values Therefore by analyzing the system's code that uses configuration values one can understand and make use of system level information of configurations to build defense against potential errors This dissertation first presents Spex that enables systems to anticipate misconfigurations Spex automatically infers configuration constraints from a system's source code and then leverages the constraints to test the system's resilience to misconfigurations and detect error prone configuration design handling On step further the dissertation introduces PCheck to automatically generate checking code which captures configuration errors at the system's initialization phase to prevent their late manifestations and the corresponding failure damage Going beyond this dissertation presents simplicity oriented configuration design towards more usable and less error prone software configuration The key idea is to apply the user centric philosophy to design configuration as an interface configurations are essentially the interface for controlling and customizing system behavior but have rarely been treated as it is The dissertation shows that configurations in today's systems software can be significantly simplified and effectively navigated with the understanding of how they are actually used in the field
