ABSTRACT: This paper outlines an approach to Bayesian semiparametric regression in multiple equation models which can be used to carry out inference in seemingly unrelated regressions or simultaneous equations models with nonparametric components. The approach treats the points on each nonparametric regression line as unknown parameters and uses a prior on the degree of smoothness of each line to ensure valid posterior inference despite the fact that the number of parameters is greater than the number of observations. We derive an empirical Bayesian approach that allows us to estimate the prior smoothing hyperparameters from the data. An advantage of our semiparametric model is that it is written as a seemingly unrelated regressions model with independent Normal-Wishart prior. Since this model is a common one, textbook results for posterior inference, model comparison, prediction and posterior computation are immediately available. We use this model in an application involving a two-equation structural model drawn from the labor and returns to schooling literatures.

Bayesian Non-linear Methods for Survival Analysis and Structural Equation Models Zhenyu Wang (Statistician), 2014 High dimensional data are more common nowadays because the collection of such data becomes larger and more complex due to the technology advance of the computer science biology etc The analysis of high dimensional data is different from traditional data analysis and variable selection for high dimensional data becomes very challenging Structural equation modeling SEM analyzes the relationship between manifest variables and latent variables The structural equation focuses on analyzing the relationship between latent variables New proposed methods of these topics are discussed in the dissertation In the first chapter we review the basic concept of survival analysis SEM and current method of variable selection in those two scenarios We also introduce the available software package for current methods and relevant

data set In the second chapter we develop a Bayesian kernel machine model with incorporating existing information on pathways and gene networks in the analysis of DNA microarray data Each pathway is modeled nonparametrically using reproducing kernel Hilbert space The pathways and the genes are selected via assigning mixture priors on the pathway indicator variable and the gene indicator variable This approach helped us in flexible modeling of the pathway effects which can capture both linear and non linear effect Moreover the model can also pinpoint the important pathways and the important active genes within each pathway We have also developed an efficient Markov Chain Monte Carlo MCMC algorithm to fit our model We used simulations and a real data analysis van t Veer et al 2002 breast cancer microarray data to illustrate the proposed method In the third chapter we extend the idea of semiparametric structural equation model where the nonlinear functional relationships are approximated using basis expansions Guo et al 2012 Many basis expansion methods including cubic splines are known to induce correlations In this chapter we compare standard Lasso Fused Lasso and Elastic Net to account for correlations in both the covariate and basis expansions To illustrate the usefulness of the proposed methods a simulation study and a real data study have been performed The semiparametric structural equation models based on Bayesian fused Lasso and Bayesian elastic net outperform the Bayesian Lasso model In the fourth chapter we apply Bayesian Graph Laplacian Model developed by Liu et al 2014 and generalized the graph Laplacian allowing both positively and negatively correlated variable to analyze gene expression data from Michigan prostate cancer study Dhanasekaran et al 2001 We find out the underlie gene network and interaction related to prostate cancer and discuss the possible extensions for Bayesian Graph Laplacian Model including analyzing multiple pathways simultaneously and pathways selection right censored data as response variable and binomial or multinomial data as response variable

Mathematical Reviews, 2006 **Latent Variable Models for Multiple Longitudinal Outcomes with Non-ignorable Missing Data** Xiaohong Yan, 2007 **Statistical Theory and Method Abstracts**, 1997 Bayesian Estimation and Testing of Structural Equation Models Richard Scheines, Herbert Hoijtink, Anne Boomsma, 1995 Abstract The Gibbs sampler can be used to obtain samples of arbitrary size from the posterior distribution over the parameters of a structural equation model given covariance data and a prior distribution over the parameters Point estimates standard deviations and interval estimates for the parameters can be computed from these samples If the prior distribution over the parameters is uninformative the posterior is proportional to the likelihood and asymptotically the inferences based on the Gibbs sample are the same as those based on the maximum likelihood solution e.g. output from LISREL or EQS In small samples however the likelihood surface is not multivariate normal and in some cases not even unimodal Nevertheless the Gibbs sampler draws a sample from the true posterior distribution over the parameters regardless of the sample size and the shape of the likelihood surface With an informative prior distribution over the parameters it can be used to estimate underidentified models as we illustrate on a simple errors in variables model

Structural Equation Models Georgian Federation of Psychologists Academic Team, Structural Equation Modeling has emerged as a powerful statistical technique for analyzing complex relationships in social science research It allows researchers to simultaneously examine the relationships between multiple latent variables while also considering the impact of measurement error Lei Wu 2007 Lee et al 2018 Structural Equation Modeling provides a framework for testing hypotheses about the underlying mechanisms that drive various social phenomena making it a valuable tool for researchers in fields such as psychology sociology and education One of the key benefits of Structural Equation Modeling is its ability to handle latent variables which are unobserved constructs that cannot be directly measured but can be inferred from observable indicators This is particularly useful in the social sciences where many of the variables of interest are not directly observable such as intelligence attitudes or personality traits By incorporating these latent variables into the model researchers can gain a more comprehensive understanding of the relationships between different constructs and how they interact Structural Equation Modeling typically involves two main components the measurement model and the structural model The measurement model specifies the relationships between the latent variables and their observed indicators while the structural model examines

the relationships between the latent variables themselves One of the key steps in conducting a Structural Equation Modeling analysis is the specification of the model This involves the researcher defining the relationships between the variables based on their theoretical understanding of the phenomenon being studied Once the model has been specified the researcher can then estimate the parameters of the model using a variety of statistical techniques such as maximum likelihood or robust weighted least squares A comprehensive understanding of Structural Equation Modeling requires a solid grounding in statistical theory and an understanding of the various assumptions and limitations of the technique
