The aim of this book is to provide an application-oriented introduction to digital signal processing. The book's emphasis is more on signal processing than on discrete-time system theory, but the basic principles of the latter are adequately covered. The guiding philosophy and objective in writing this text were the weaving into the material of several applications and worked examples, computer simulations that illustrate the basic digital signal-processing concepts.

The book includes twelve chapters, four appendices, references structured on different subjects, and an index. Chapter 1 is devoted to the basic issues of sampling, aliasing and analog reconstruction, at a level appropriate for juniors, and to the practical issues of choosing and defining specifications for anti-aliasing prefilters and anti-image postfilters, at an advanced level.

Chapter 2 discusses the quantization process and some practical implementations of A/D and D/A converters, such as the conversion algorithm for bipolar two's complement successive approximation converters. The standard model of quantization noise is presented, as well as the techniques of oversampling, noise shaping and dithering; the trade-off between oversampling ratio and savings in bits is also derived. Chapter 3 provides a review of basic discrete-time system concepts such as linearity, time-invariance, impulse response, convolution, FIR and IIR filters, causality and stability.

Chapter 4 presents the FIR filters, and introduces two basic signal-processing methods: block-by-block processing and sample-by-sample processing. In the first part, various approaches to convolution, transient and steady-state behaviour of filters, and real-time processing on a block-by-block basis using the overlap-add method and its software implementation are discussed. In the second part of the chapter, the basic building blocks of filters: adders, multipliers, and delays, are introduced, the block diagrams for

FIR filters and their time-domain operation on a sample-by-sample basis are discussed, and the concept of a sample-processing algorithm is emphasized. The concept of circular buffers, and their use in implementing delays and FIR filters, is also discussed.

Chapter 5 is devoted to basics of the z -transform: convergence, causality, stability and frequency spectrum. Chapter 6 discusses the characterization of a linear filter in various equivalent ways, and illustrates their use by examples. Other topics, such as sinusoidal and steady-state responses, time constants of filters, simple pole/zero designs of first- and second-order filters, as well as comb and notch filters, are presented. Chapter 7 develops the standard filter realizations of canonical, direct, and cascade forms. Implementation with linear and circular buffers, and the quantization effects, are also discussed.

Chapter 8 presents three application areas of digital signal processing: digital waveform generation (including sinusoidal, periodic waveform and wavetable generators), digital audio effects (such as flanging, chorusing, reverberation and multitap delays), dynamic processors (such as compressors, limiters, expanders and gates), and noise reduction/signal enhancement, as one of the most important applications. For this latter application, the basic principles involved in designing noise-reduction and signal-enhancement filters, in both the frequency and the time domain, are presented. The design and circular buffer implementation of notch and comb filters, with applications in removing periodic interference, enhancing periodic signals, signal averaging, and separating the luminance and chrominance components in digital color TV systems are discussed. A distinct problem treated in this chapter is data smoothing and differentiation using Savitzky-Golay filters.

Chapter 9 is devoted to DFT/FFT algorithms. After a discussion of the issues of spectral analysis, frequency resolution, windowing and leakage, the computational aspects of DFT and some of its pitfalls, the difference between physical and computational frequency resolution, the FFT, and fast convolution are presented. Chapter 10 is dedicated to FIR filter design by the window method, with emphasis on the Kaiser window. The use of this window in spectral analysis is also discussed. Chapter 11 presents IIR filter design using bilinear transformation based on Butterworth and Chebyshev filters. It is shown how to design practical second-order digital audio parametric equalizer filters with prescribed widths,
