**Convex Optimization Via Domain-driven Barriers and Primal-dual Interior-point Methods** Mehdi Karimi, 2017 This thesis studies the theory and implementation of infeasible start primal dual interior point methods for convex optimization problems Convex optimization has applications in many fields of engineering and science such as data analysis control theory signal processing relaxation and randomization and robust optimization In addition to strong and elegant theories the potential for creating efficient and robust software has made convex optimization very popular Primal dual algorithms have yielded efficient solvers for convex optimization problems in conic form over symmetric cones linear programming LP second order cone programming SOCP and semidefinite programming SDP However many other highly demanded convex optimization problems lack comparable solvers To close this gap we have introduced a general optimization setup called emph Domain Driven that covers many interesting classes of optimization Domain Driven means our techniques are directly applied to the given good formulation without a forced reformulation in a conic form Moreover this approach also naturally handles the cone constraints and hence the conic form A problem is in the Domain Driven setup if it can be formulated as minimizing a linear function over a convex set where the convex set is equipped with an efficient self concordant barrier with an easy to evaluate Legendre Fenchel conjugate We show how general this setup is by providing several interesting classes of examples LP SOCP and SDP are covered by the Domain Driven setup More generally consider all convex cones with the property that both the cone and its dual admit efficiently computable self concordant barriers Then our Domain Driven setup can handle any conic optimization problem formulated using direct sums of these cones and their duals Then we show how to construct interesting convex sets as the direct sum of the epigraphs of univariate convex functions This construction as a special case contains problems such as geometric programming p norm optimization and entropy programming the solutions of which are in great demand in engineering and science Another interesting class of convex sets that optimization over it is contained in the Domain Driven setup is the generalized epigraph of a matrix norm This as a special case allows us to minimize the nuclear norm over a linear subspace that has applications in machine learning and big data Domain Driven setup contains the combination of all the above problems for example we can have a

problem with LP and SDP constraints combined with ones defined by univariate convex functions or the epigraph of a matrix norm We review the literature on infeasible start algorithms and discuss the pros and cons of different methods to show where our algorithms stand among them This thesis contains a chapter about several properties for self concordant functions Since we are dealing with general convex sets many of these properties are used frequently in the design and analysis of our algorithms We introduce a notion of duality gap for the Domain Driven setup that reduces to the conventional duality gap if the problem is a conic optimization problem and prove some general results Then to solve our problems we construct infeasible start primal dual central paths A critical part in achieving the current best iteration complexity bounds is designing algorithms that follow the path efficiently The algorithms we design are predictor corrector algorithms Determining the status of a general convex optimization problem as being unbounded infeasible having optimal solutions etc is much more complicated than that of LP We classify the possible status seven possibilities for our problem as solvable strictly primal dual feasible strictly and strongly primal infeasible strictly and strongly primal unbounded and ill conditioned We discuss the certificates our algorithms return heavily relying on duality for each of these cases and analyze the number of iterations required to return such certificates For infeasibility and unboundedness we define a weak and a strict detector We prove that our algorithms return these certificates solve the problem in polynomial time with the current best theoretical complexity bounds The complexity results are new for the infeasible start models used The different patterns that can be detected by our algorithms and the iteration complexity bounds for them are comparable to the current best results available for infeasible start conic optimization which to the best of our knowledge is the work of Nesterov Todd Ye 1999 In the applications computation and software front based on our algorithms we created a Matlab based code called DDS that solves a large class of problems including LP SOCP SDP quadratically constrained quadratic programming QCQP geometric programming entropy programming and more can be added Even though the code is not finalized this chapter shows a glimpse of possibilities The generality of the code lets us solve problems that CVX a modeling system for convex optimization does not even recognize as convex The DDS code accepts constraints representing the epigraph of a matrix norm which as we mentioned covers minimizing the nuclear norm over a linear subspace For acceptable classes of convex optimization problems we explain the format of the input We give the formula for computing the gradient and Hessian of the corresponding self concordant barriers and their Legendre Fenchel conjugates and discuss the methods we use to compute them efficiently and robustly We present several numerical results of applying the DDS code to our constructed examples and also problems from well known libraries such as the DIMACS library of mixed semidefinite quadratic linear programs We also discuss different numerical challenges and our approaches for removing them
