The hashgraph data structure and gossip consensus algorithm provide unique properties for distributed consensus. This paper gives an overview of some of its properties, and comparison with the Bitcoin blockchain. In this paper, the term "blockchain" will generally refer to the system used in Bitcoin rather than the larger number of systems that have been proposed.

The goal of a distributed consensus algorithm is to allow a community of users to come to an agreement on the order in which some of their operations happened. In Bitcoin, these operations are treated as transactions. In this sense, it is a system for coordinating what others consider to be and already had such as. The Swirlds hashgraph system achieves this along with being able to generate Byzantine fault resistant consensus, Byzantine fault tolerant, Byzantine fault tolerant and Byzantine fault tolerant. This is a technical paper.

The hashgraph is distributed across all individual nodes comprising the system. For example, imagine a stock market where Alice and Bob both try to buy the last available share of a stock at the same moment for the same price. In Bitcoin, it does not get both their transactions in a single block, and some complete transactions to show what each does. In the hashgraph, Alice and Bob's transactions are included in a single block. In the hashgraph, there is no need for any individual to affect the consensus order of those transactions. The hashgraph can be treated as a graph where consensus is that the transactions receive everyone's approval. That's the fair way to compare. Alice can't do this to force the order to give her an unfair advantage, because that is an illegal action. Responsibility for the order.
