**Mendelian Randomization: the Study of Causal Relationships between Tumors and Underlying Pathogenic Factors** Ziheng Wang, Guangsheng Pei,2025-05-15 The malignant tumor is a major global public health problem threatening human health At present association studies can be used to analyze the occurrence and development of tumors Association studies such as the classic study of smoking and lung cancer and the popular genome wide association study GWAS form the basis of medical research These studies provided initial evidence for subsequent mechanistic exploration and functional studies but could not illustrate a causal relationship R A Fisher first proposed the concept and method of Mendelian randomization MR in a 1936 book called The Design of Experiments Based on the principles of Mendelian genetics he regarded randomly assigned genotypes as natural randomization experiments to evaluate the causal effect of a factor on a particular phenotypic trait Mendelian randomization MR is a statistical method based on whole genome sequencing data GWAS which can effectively reduce bias and is used to reveal causality similar to randomized controlled trials RCT MR can be used to evaluate causal inference using genetic variants as instrumental variables to represent specific exposures infer causal relationships between exposures and outcomes and transform phenotype to genotype causal studies into genotype studies The advantage is that an individual's genetic variation precedes the outcome of a disease which eliminates confounding bias due to reverse causality Modern

bioinformatics techniques can measure genetic variation with high precision which largely reduces the estimation bias caused by measurement errors
