Large-scale Wireless Networks Junghoon Lee,2014 Recently the location of the nodes in wireless networks has been modeled as point processes In this dissertation various scenarios of wireless communications in large scale networks modeled as point processes are considered The first part of the dissertation considers signal reception and detection problems with symmetric alpha stable noise which is from an interfering network modeled as a Poisson point process For the signal reception problem the performance of space time coding STC over fading channels with alpha stable noise is studied We derive pairwise error probability PEP of orthogonal STCs For general STCs we propose a maximum likelihood ML receiver and its approximation The resulting asymptotically optimal receiver AOR does not depend on noise parameters and is computationally simple and close to the ML performance Then signal detection in coexisting wireless sensor networks WSNs is considered We define a binary hypothesis testing problem for the signal detection in coexisting WSNs For the problem we introduce the ML detector and simpler alternatives The proposed mixed fractional lower order moment FLOM detector is computationally simple and close to the ML performance Stochastic orders are binary relations defined on probability The second part of the dissertation introduces stochastic ordering of interferences in large scale networks modeled as point processes Since closed form results for the interference distributions for such networks are only available in limited cases it is of interest to compare network interferences using stochastic In this dissertation conditions on the fading distribution and path loss model are given to establish stochastic ordering between interferences Moreover Laplace functional LF ordering is defined between point processes and applied for comparing interference Then the LF orderings of general classes of point processes are introduced It is also shown that the LF ordering is preserved when independent operations such as marking thinning random translation and superposition are applied The LF ordering of point processes is a useful tool for comparing spatial deployments of wireless networks and can be used to establish comparisons of several performance metrics such as coverage probability achievable rate and resource allocation even when closed form expressions for such metrics are unavailable

Modeling and Analyzing Wireless Networks Using Stochastic Geometry Junse Lee,2018 Over the past decade stochastic geometric models and most notably the planar Poisson point process PPP model have become popular for the analysis of spectral efficiency in wireless networks in both the D2D and the cellular contexts 1 By modeling base station BS and user locations as spatial point processes stochastic geometry has recently been recognized as a tractable and efficient analytical tool to quantify key performance metrics This tool provides a natural way of defining and computing macroscopic properties of multiuser information theory These properties are obtained by averaging over all node patterns found in a large random network of the Euclidean plane For example some key performance metrics such as signal to interference and noise ratio and data rate depend on the network geometric configurations This tool has thus been widely adopted for analyzing the network performance and broadening network design This thesis proposes new models to represent several new scenarios Three main scenarios are considered 3 D inbuilding networks MIMO adhoc networks and multihop communication under mmWave networks To do so mathematical tools such as Poisson point processes Poisson line processes Boolean models and Poisson bipolar models are used Each model is 1 generative in that it has a clear physical interpretation 2 leads to explicit analytical representations of important wireless performance metrics and 3 highly parametric with parameters expressing the geometric characteristic of the elements of networks Physical interpretations from these models are quite different from previous results The core of this thesis is focused on the effects of correlated shadowing Shadowing is the effect that the received signal power fluctuates due to objects obstructing the propagation path By introducing an independent shadowing term over links it is possible to model the effect of shadow fading Most previous papers analyzing urban networks assume that shadowing fields are independent over links With this assumption it is possible to derive simple closed form expressions of important network performance metrics However this assumption cannot capture that shadowing fields are spatially correlated This thesis goes beyond the independent shadowing approximation and analyzes the effects of correlated shadowing on various performance metrics

Stochastic Geometry for Modeling, Analysis and Design of Future Wireless Networks Jing Guo,2016 This thesis focuses on the modeling analysis and design of future wireless networks with smart devices i e devices with intelligence and ability to communicate with one another with without the control of base stations BSs Using stochastic geometry we develop realistic yet tractable frameworks to model and analyze the performance of such networks while incorporating the intelligence features of smart devices In the first half of the thesis we develop stochastic geometry tools to study arbitrarily shaped network regions Current techniques in the literature assume the network regions to be infinite while practical network regions tend to be arbitrary Two well known networks are considered

where devices have the ability to i communicate with others without the control of BSs i e ad hoc networks and ii opportunistically access spectrum i e cognitive networks First we propose a general algorithm to derive the distribution of the distance between the reference node and a random node inside an arbitrarily shaped ad hoc network region which helps to compute the outage probability We then study the impact of boundary effects and show that the outage probability in infinite regions may not be a meaningful bound for arbitrarily shaped regions By extending the developed techniques we further analyze the performance of underlay cognitive networks where different secondary users SUs activity protocols are employed to limit the interference at a primary user Leveraging the information exchange among SUs we propose a cooperation based protocol We show that in the short term sensing scenario this protocol improves the network s performance compared to the existing threshold based protocol In the second half of the thesis we study two recently emerged networks where devices have the ability to i communicate directly with nearby devices under the control of BSs i e device to device D2D communication and ii harvest radio frequency energy i e energy harvesting networks We first analyze the intra cell interference in a finite cellular region overlaid with D2D communication by incorporating a mode selection scheme to reduce the interference We derive the outage probability at the BS and a D2D receiver and propose a spectrum reuse ratio metric to assess the overall D2D communication performance We demonstrate that without impairing the performance at the BS if the path loss exponent on cellular link is slightly lower than that on D2D link the spectrum reuse ratio can have negligible decrease while the average number of successful D2D transmissions increases with the increasing D2D node density This indicates that an increasing level of D2D communication is beneficial in future networks Then we study an ad hoc network with simultaneous wireless information and power transfer in an infinite region where transmitters are wirelessly charged by power beacons We formulate the total outage probability in terms of the power and channel outage probabilities The former incorporates a power activation threshold at transmitters which is a key practical factor that has been largely ignored in previous work We show that although increasing power beacon s density or transmit power is not always beneficial for channel outage probability it improves the overall network performance

On Large Cooperative Wireless Network Modeling Through a Stochastic Geometry Approach Andres Oscar Altieri, 2014 The main goal of this work is to study cooperative aspects of large wireless networks from the perspective of stochastic geometry This allows the consideration of important effects such as the random spatial distribution of nodes as well as the effects of interference and interference correlation at receivers which are not possible when a single link is considered in isolation First some aspects of the performance of the relay channel in the context of a large wireless network are considered Mainly the performance in terms of outage probability OP of a single full duplex relay channel utilizing decode and forward DF or compress and forward when the interference is generated by uniform spatial deployment of nodes modeled as a Poisson point process The OP performance of these two protocols is compared with a point to point transmission and with a half duplex DF protocol Afterwards the case in which more than one transmitter in the network may use a relay is considered The effects of cooperation versus interference are studied when the users use either full duplex DF or point to point transmissions In a second phase this work explores the advantages that could be obtained through out of band device to device D2D video file exchanges in cellular networks These advantages are measured in terms of the fraction of requests that can be served in a time block through D2D thus avoiding a downlink file transfer from the base station For

this a stochastic geometry framework is introduced in which the user file caching policy user pairing strategy and link quality and scheduling issues are considered

Throughput Characterizations of Wireless Networks Via Stochastic Geometry and Random Graph Theory Jeffrey William Wildman (II), 2015 The shared medium of wireless communication networks presents many technical challenges that offer a rich modeling and design space across both physical and scheduling protocol layers This dissertation is organized into tasks that characterize the throughput performance in such networks with a secondary focus on the interference models employed therein We examine the throughput ratio of greedy maximal scheduling GMS in wireless communication networks modeled as random graphs A throughput ratio is a single parameter characterization of the largest achievable fraction of the network capacity region The throughput ratio of GMS is generally very difficult to obtain however it may be evaluated or bounded based on specific topology structures We analyze the GMS throughput ratio in previously unexplored random graph families under the assumption of primary interference Critical edge densities are shown to yield bounds on the range and expected GMS throughput ratio as the network grows large We next focus on the increasing interest in the use of directional antennas to improve throughput in wireless networks We propose a model for capturing the effects of antenna misdirection on coverage and throughput in large scale directional networks within a stochastic geometry framework We provide explicit expressions for communication outage as a function of network density and antenna beamwidth for idealized sector antenna patterns These expressions are then employed in optimizations to maximize the spatial density of successful transmissions under ideal sector antennas We supplement our analytical findings with numerical trends across more realistic antenna patterns Finally we characterize trade offs between the protocol and physical interference models each used in the prior tasks A transmission is successful under the protocol model if the receiver is free of any single significant interferer while physical model feasibility accounts for multiple interference sources The protocol model parameterized by a guard zone radius naturally forms a decision rule for estimating physical model feasibility We combine binary hypothesis testing with stochastic geometry and characterize the guard zone achieving minimum protocol model prediction error We conclude with guidelines for identifying environmental parameter regimes for

Analysis Using Stochastic Geometry Jeffrey G. Andrews, Abhishek K. Gupta, Ahmad Alammouri, Harpreet S.

Dhillon, 2023-06-30 This book provides an accessible yet rigorous first reference for readers interested in learning how to model and analyze cellular network performance using stochastic geometry. In addition to the canonical downlink and uplink settings, analyses of heterogeneous cellular networks and dense cellular networks are also included. For each of these settings, the focus is on the calculation of coverage probability, which gives the complementary cumulative distribution function (ccdf) of signal to interference and noise ratio (SINR) and is the complement of the outage probability. Using this, other key performance metrics such as the area spectral efficiency are also derived. These metrics are especially useful in understanding the effect of densification on network performance. In order to make this a truly self-contained reference, all the required background material from stochastic geometry is introduced in a coherent and digestible manner. This book provides an approachable introduction to the analysis of cellular networks and illuminates key system dependencies. Features an approach based on stochastic geometry as applied to cellular networks, including both downlink and uplink. Focuses on the statistical distribution of signal to interference and noise ratio (SINR) and related metrics.

A Stochastic Geometry Analysis of Cooperative Wireless Networks Powered by Energy Harvesting Talha Ahmed Khan, 2015 Energy harvesting technology is essential for enabling green, sustainable, and autonomous wireless networks. In this report, a large-scale wireless network with energy harvesting transmitters is considered, where a group of transmitters forms a cluster to cooperatively serve a desired user in the presence of co-channel interference and noise. Using stochastic geometry, simple closed-form expressions are derived to characterize the outage performance at the user as a function of important parameters such as the energy harvesting rate, the energy buffer size, and the cluster size for a given cluster geometry. The analysis is further extended to characterize the delay due to transmission failure. The developed framework is flexible in that it allows the in-cluster transmitters to have possibly different energy harvesting capabilities. The analytical expressions are first validated using simulations and then used for investigating the impact of different parameters such as cluster and buffer size on outage performance. The results suggest that substantial outage performance can, in fact, be extracted with a relatively small energy buffer. Moreover, the utility of having a large energy buffer increases with the cluster size as well as with the energy harvesting rate.
