

3D FINITE ELEMENT MODEL FOR ASPHALT CONCRETE RESPONSE SIMULATION

S.M.J.G. Erkens¹, X. Liu² and A. Scarpas³

ABSTRACT

An extensive experimental, analytical and numerical investigation on the response of asphalt concrete is currently in progress at Delft University of Technology. The objectives of this Asphalt Concrete Response (ACRe) project are: (a) the formulation and finite element implementation of a 3-dimensional, strain rate sensitive, temperature and loading history dependent constitutive model, (b) the development of the necessary experimental set-ups, testing procedures and data-analysis methods for determination of the model parameters.

These objectives are strongly interrelated: on the one hand the model dictates what should be measured in a test, while on the other hand, the response observed in the tests sets the requirements for the model. As a result, model development/verification and experimental testing have been progressing in parallel throughout the project. In this contribution both, the finite element and the experimental aspects of the project will be presented.

The constitutive model has been implemented in the finite element system INSAP. The system has been used to simulate the initiation and propagation of damage in two flexible pavement structures due to repeated loading. The simulations illustrate the influence of geometry and material characteristics on the development of damage.

Key words: 3D, material model, response simulation, material parameter determination

1 INTRODUCTION

Most of the design procedures that are used in road engineering are based on linear elastic multi-layer analysis and simple laboratory tests. Unfortunately, design life and material degradation, which are essential issues in estimating the life time of a pavement, can not be addressed by linear elasticity. In the damage accumulation process the complex nature of asphalt concrete is essential and accurate performance predictions are possible only when that nature is modelled. This means that, besides the temperature and strain rate dependency, the state of stress dependency of the material response must be also taken into account. So far, this is often neglected although it is well known that the strength of asphalt concrete increases with increasing confinement. When it comes to failure predictions, this aspect of the material behaviour can no longer be neglected. The multitude of states of stress caused by a wheel load results in a multitude of different material strengths. As a result, the damage accumulation process is highly complex, since it depends not only on the material characteristics but also on the state of stress.

Mechanistic Model to Predict the Impact of the Aggregate Matrix on the Permanent Deformation of Asphalt Mixtures Samer Hassan Dessouky, Eyad Masad, Dallas N. Little, 2005 Hot mix asphalt HMA is a granular composite material stabilized by the presence of asphalt binder The behavior of HMA is highly influenced by the microstructure distribution in terms of the different aggregate particles present in the mix the directional distribution of aggregates the distribution of voids and the nucleation and propagation of cracks Conventional continuum modeling of HMA lacks the ability to explicitly account for the effect of aggregate microstructure distribution features This report presents the development of elastic and visco plastic models that account for important aspects of the aggregate and microstructure distribution in modeling the macroscopic behavior of HMA The objective of Project 0 1707 is to develop tools by which engineers can judge the impact of the aggregate on the performance of HMA based on simple and repeatable tests Of greatest concern in Project 0 1707 is the ability of the HMA to resist permanent deformation or to rut which leads to safety concerns especially under wet surface conditions In this report the research team develops an approach is developed to introduce a length scale to the elasticity constitutive relationship in order to capture the influence of aggregate particle sizes on HMA response A finite element FE analysis is used to analyze the microstructure response and predict the macroscopic properties of HMA Each point in the microstructure is assigned effective local properties that are calculated using an analytical micromechanical model that

captures the influence of the number of particles on the microscopic response of the HMA. The moving window technique and autocorrelation function are used to determine the microstructure characteristic length scales that are used in strain gradient elasticity. A number of asphalt mixes with different aggregate types and size distributions are analyzed. An elasto-visco-plastic continuum model is developed to predict HMA response and performance. The model incorporates a Drucker-Prager yield surface that is modified to capture the influence of stress path direction on the material response. Parameters that reflect the directional distribution of aggregates and damage density in the microstructure are included in the model. The elasto-visco-plastic model is converted into a numerical formulation and is implemented in FE analysis using a user-defined material subroutine UMAT. A fully implicit algorithm in time step control is used to enhance the efficiency of the FE analysis. The FE model used in this project simulates experimental data and pavement section.

Evaluation of Effects of Tire Size and Inflation Pressure on Tire Contact Stresses and Pavement Response, 2006. A specific objective was to establish how tire contact stresses may be modeled in existing layered elastic programs to better approximate the effects of non-uniform tire contact pressure distributions and account for differences in tire construction, tire load, and tire inflation pressure on predicted pavement response. To this end, researchers assembled a data base of measured tire contact stresses and performed a comparative evaluation of methods for representing tire contact pressure distributions in existing models to predict performance-related pavement response variables. A computer program called TireView was developed that provides estimates of tire contact area as a function of tire type, tire load, and tire inflation pressure and predicts the stress distribution at the tire-pavement interface based on polynomial interpolations of measured tire contact stresses in the data base. A method for predicting pavement response using layered elastic analysis is proposed that is based on the predicted tire contact area.

Establishment of Subgrade Undercut Criteria and Performance of Alternative Stabilization Measures Roy H. Borden, 2010. The scope of this research includes the development of criteria to define the need for undercutting the depth of the undercut and the quality of the backfill material such that the cost and performance are optimized. In addition, chemical stabilization and geosynthetic reinforcement in combination with several thicknesses of the ABC were studied to provide comparative criteria for the enhancement of various poor subgrade soils encountered in N C with or in lieu of undercut and replacement with select fill. The criteria are presented along with the associated relative costs of each alternative.

Evaluation of Asphalt Concrete Pavement Service Life Using 3D Nonlinear Finite Element Analysis and Nonlinear Fatigue Damage Model Zhi Suo, Hong Kong Polytechnic University, Department of Civil and Structural Engineering, 2012. A study has been conducted at Hong Kong Polytechnic University to develop a procedure to better predict long-term performance of asphalt concrete pavements. To achieve this end, complicated finite element

techniques are employed and parametric studies are performed The fatigue destructive mechanics fracture mechanics and damage mechanics are used to develop a 3D Finite element model that can be applied to characterize the nonlinear properties of the asphalt concrete materials A set of materials tests is performed to evaluate various bituminous wearing course materials by using Universal Servo Pneumatic Testing System in Hong Kong Road Research Laboratory such as indirect tensile modulus dynamic creep indirect tensile fatigue and wheel tracking The materials for this study comprise conventional asphalt concrete wearing course ACWC and stone mastic asphalt SMA with a virgin 60 70 bitumen and different modified bitumen Polypropylene Crumb rubber Cellulose fiber Asbestos fiber and Gilsonite The test results are analyzed in a multiple regression technique to capture the parameters in the proposed creep model With the developed materials models the typical flexible pavement structures are modeled in the finite element software ANSYS The real vehicle loads are employed and the effects of the footprint shape loading frequency and curing time are studied by using this computer simulation technique The simulation results show that the SMA has a better healing effect and a longer micro damage fatigue life than other mixtures with significantly enhanced healing effect In addition after the fatigue analysis and the prediction of the service life of flexible pavement a sensitivity analysis is conducted to investigate the effect of cross section and load attributes factors on pavement response
